Thanks, Madhuresh Kumar PichamuthuQ: Unable to

use AngularJS in Visual Studio 2015 I have created

an AngularJS application in Visual Studio 2015 and

after having installed it, added AngularJS script

references in the view: `{{ JSON.stringify(jsonData)`

`}} {{ name }}` The application seems to work fine,

but when I try to debug it, I get an error on view/control : And when I inspect the element, I see the following error: On Google Chrome, I see this in the Console: `FileError: [$injector:modulerr] Failed to instantiate module angularjs due to: [$injector:nomod] Module 'angularjs' is not available! You either misspelled the module name or forgot to load it. If registering a module ensure that you specify the dependencies as the second argument. at angular.js:46 at loadModules (angular.js:15876) at angular.js:16472 at dc (angular.js:5178) at F (angular.js:4750) at c (angular.js:4634) at HTMLDocument.e (angular.js:4864) at angular.js:4032` Help please, I have been staring at the errors for a while now and can't find any solution. A: As simple as this, just install this package: That's all. A: Solution found, post it as answer if anyone ever encounters this. I realized that Karma is the one causing trouble, as my projects had other projects configured which also had Karma installed. In my project in question, I disabled Karma, first by removing the following (generated by Bower):

I am working on a project in Java and I'm having a very difficult time understanding the ins and outs of object-oriented programming. What I am attempting to do is make a simple program that will simulate the Earth's rotation so that a moving object can be displayed on a graphics window. I feel like I'm getting closer and closer to the answer, but I keep running into the same problems. I apologize in advance for the long wall of text, I'd appreciate any

tips or advice from the experts! Ok, so what I've got so far is a rotation class with no methods, but I think that's not important. What I'm trying to do now is to have a method within the rotation class that determines the next "time" that object will roll on the Earth's surface. I'm having a hard time even understanding what this means, I don't understand how to define this method using variables and if I'm going about it correctly at all. I'm not really sure how to show you my code and explain it, so I'm just going to post the most relevant parts. In my main class I create an instance of the rotation class and set the initial time value when the program starts (7.84992e8 ms). To find the next "time", I would imagine the algorithm could work something like this: so, I imagine the time variable is always changing, meaning the function calls are being made every 5 milliseconds. In order to find the time until the object next happens to be on the surface, I would assume I could find the time at f678ea9f9e
